Abstract: This paper presents a new method for the automatic detection of the onset of a seizure. The method is based on the analysis of the EEG signal. The onset of a seizure is detected by the analysis of the power spectrum of the EEG signal. The power spectrum is calculated for each 1-second segment of the EEG signal. The power spectrum is then compared with a reference power spectrum. The reference power spectrum is calculated from the power spectrum of the EEG signal before the onset of the seizure. The power spectrum of the EEG signal after the onset of the seizure is compared with the reference power spectrum. The difference between the power spectrum of the EEG signal after the onset of the seizure and the reference power spectrum is calculated. The difference is then compared with a threshold. If the difference is greater than the threshold, the onset of a seizure is detected. The method is evaluated using a set of EEG signals. The results show that the method is able to detect the onset of a seizure with a high accuracy.
